1 Theoretical Background

1.1 General Analytical Solution

The wave equation (WE) for the scalar field $\phi(t, x)$ in one spatial and one time dimension is

$$0 = \frac{\partial^2 \phi}{\partial t^2} - c^2 \frac{\partial^2 \phi}{\partial x^2} = \partial_{tt}\phi - c^2 \partial_{xx}\phi \tag{1}$$

with $c \in \mathbb{R}$. According to the symmetry of second derivatives this can be divided into two factors

$$0 = (\partial_t - c\partial_x)(\partial_t + c\partial_x)\,\phi \ . \tag{2}$$

With introduction of two variables, $\xi = x - ct$ and $\nu = x + ct$, now we can write:

$$0 = \partial_\xi \partial_\nu \phi \ . \tag{3}$$

Therefor the wave equation has the general solution

$$\phi(t, x) = f(\xi) + g(\nu) = f(x - ct) + g(x + ct) \tag{4}$$

which is a composition of a forward and a backward propagating elementary wave. As boundary condition we assume the initial time value and its derivative:

$$\phi_0(x) = \phi(0, x) = f(x) + g(x) =: A(x) \tag{5}$$

$$\Big(\partial_t \phi(0, x)\Big) = cf'(x) - cg'(x) =: B(x) \ . \tag{6}$$

Integrating eq. 6 results in

$$f(x) - g(x) = \int_{x_0}^{x} B(s)\,\mathrm{d}s \tag{7}$$

so that the separated solution is given by (here $x_0 = x(t = 0)$)

$$f(x) = \frac{1}{2}\left(A(x) + \frac{1}{c}\int_{x_0}^{x} B(s)\,\mathrm{d}s\right) \tag{8}$$

$$g(x) = \frac{1}{2}\left(A(x) - \frac{1}{c}\int_{x_0}^{x} B(s)\,\mathrm{d}s\right) \ . \tag{9}$$

Putting these together yields the general solution in dependence of the initial values, the d'Alembert's formula:

$$\phi(t, x) = \frac{1}{2}\left(A(x - ct) + A(x + ct) + \frac{1}{c}\int_{x-ct}^{x+ct} B(s)\,\mathrm{d}s\right) \tag{10}$$

This means, for given initial parameters the wave's evolution in time is clearly defined.

1.2 Rewriting the WE as two differential equations out of one

Now we introduce the time derivative of the field as a new variable: $\Pi(t, x) = \partial_t \phi$. Thereby the initial wave equation eq. 1 can be rewritten as a wave equation including the first-order derivative in time and second-order derivative in space:

$$\partial_t \Pi = \partial_{tt}\phi = c^2 \partial_{xx}\phi \ . \tag{11}$$

Now one can, in accordance to the notation we introduced above, regard the field's derivative at the initial time $\Pi(0, x)$ as $B(x)$. Typical values for this initial velocity $\Pi(0, x)$ are either 0 or a constant.

Example 1: $\Pi(0,x) = 0$ If we consider the field's initial velocity to be zero, $\Pi(0,x) = 0$ almost everywhere, this means the wave roughly is a pulse. Furthermore, if we assume no spatial boundaries the pulse will dominate the shape of the wave as time moves forward.

Example 2: $\Pi(0,x) =$ **const.** If we consider the initial velocity to be a constant, the wave function is at rest in a suitable inertial frame of reference. Hence, there will be no wave propagation.

1.3 Rewriting the WE as a fully first order system / eigenvalue problem / Matrix form of the wave equation

Similar to the definition of the velocity variable $\Pi(t,x)$ we now introduce the slope variable as the spatial derivative of the field: $\chi = \partial_x \phi$. Thereby we can write the waveequation 1 as a first order system

$$\partial_t \vec{u} + \hat{M} \partial_x \vec{u} = \vec{S} \ . \tag{12}$$

Herein u is the state vector $\vec{u} = \{\phi, \Pi, \chi\}$, S is a source term and the matrix $\hat{M}$ can be found by simple coefficient comparision to be

$$\hat{M} = \begin{pmatrix} c & 0 & 0 \\ 0 & 0 & c^2 \\ 0 & 1 & 0 \end{pmatrix} \ .$$

The source the then is of type $S = \{\Pi + c\chi, 0, 0\}$.

1.3.1 Choices for Initial Values

???

1.3.2 Eigenvalue Problem

The matrix formulation 12 in fact is an eigenvalue problem, whichs eigenvalues can be easily found to be $\lambda_{1/2} = \pm c$. For $\lambda_1 = +c$, eigenvectors are $v_1 = \{1, 0, 0\}$ and $v_2 = \{0, c, 1\}$, for $\lambda_2 = -c$ the eigenvector is $v_3 = \{0, -c, 1\}$. Horizontally concatenated these yield the transformation matrix

$$R = \begin{pmatrix} 0 & 0 & 1 \\ -c & c & 0 \\ 1 & 1 & 0 \end{pmatrix}$$

by which we can diagonalize matrix $\hat{M}$:

$$\begin{aligned} \Lambda = \mathrm{diag}\hat{M} = R^{-1} \hat{M} R &= \begin{pmatrix} 0 & -1/2c & 1/2 \\ 0 & 1/2c & 1/2 \\ 1 & 0 & 0 \end{pmatrix} \begin{pmatrix} c & 0 & 0 \\ 0 & 0 & c^2 \\ 0 & 1 & 0 \end{pmatrix} \begin{pmatrix} 0 & 0 & 1 \\ -c & c & 0 \\ 1 & 1 & 0 \end{pmatrix} \\ &= \begin{pmatrix} -c & 0 & 0 \\ 0 & c & 0 \\ 0 & 0 & c \end{pmatrix} \end{aligned}$$

Here, one can see that the diagonalized matrix simply has the eigenvalues on the diagonal. For the eigenvalue problem $\hat{M}R = \Lambda R$ holds, so that $\hat{M} = R\Lambda R^{-1}$, which we can plug in 12:

$$\partial_t \vec{u} + R\Lambda R^{-1}\partial_x \vec{u} = \vec{S} \ . \tag{13}$$

Multiplying both sides by R^{-1} yields

$$R^{-1}\partial_t \vec{u} + \Lambda R^{-1}\partial_x \vec{u} = R^{-1}\vec{S} \ . \tag{14}$$

By introducing the new variable $w := R^{-1}\vec{u}$, this becomes

$$\partial_t w + \Lambda \partial_x w = R^{-1}\vec{S} \tag{15}$$

and we arrive at a decoupled system.
